## 1 Relativistic functions

### 1.1 lambda\_from\_eV

This function takes an energy in eV and returns the relativistic electron wavelength. The equation is shown below:

$$\lambda = \sqrt{\frac{h^2 c^2}{E^2 - m_0^2 c^2}} \quad (1)$$

### 1.2 mass\_from\_eV

Returns relativistic electron mass from kinetic energy in eV.

$$m = \sqrt{\frac{K^2 + 2Km_0c^2}{c^4}} + m_0^2 \quad (2)$$

## 2 Geometric functions

### 2.1 rotate\_vec\_array

Iterates over each vector in the  $n \times 3$  array  $\Lambda$  and rotates them around  $\hat{x}$ ,  $\hat{y}$ , then  $\hat{z}$  by  $tx$ ,  $ty$ , and  $tz$  (rad) respectively. That is,

$$\left( \forall v \in \Lambda \right) \left( v \rightarrow R_z(\theta_z) \cdot R_y(\theta_y) \cdot R_x(\theta_x) \cdot v = \mathcal{R}v \right) \quad (3)$$

**rotation\_mat** Returns a matrix corresponding to a rotation around  $\hat{x}$ ,  $\hat{y}$ , then  $\hat{z}$  by  $tx$ ,  $ty$ , and  $tz$  (rad) respectively.<sup>1</sup>

That is,

$$\mathcal{R} = R_z(\theta_z) \cdot R_y(\theta_y) \cdot R_x(\theta_x) \quad (4)$$

**rotation\_mat\_x** Returns the rotation matrix around  $\hat{x}$  by  $\theta_x$ ,  $R_x(\theta_x)$ .

**rotation\_mat\_y** Returns the rotation matrix around  $\hat{y}$  by  $\theta_y$ ,  $R_y(\theta_y)$ .

**rotation\_mat\_z** Returns the rotation matrix around  $\hat{z}$  by  $\theta_z$ ,  $R_z(\theta_z)$ .

---

<sup>1</sup>See [rotation matrices](#).

### 3 Lattice functions

#### 3.1 lattice\_populate\_single

Creates and populates a simple cubic lattice with side number  $n$ , lattice parameter  $clen$ , and centered at  $latt\_center$ .

$$\left( \forall a_i, i \in [0, n]_{\mathbb{Z}}, [0, 2]_{\mathbb{Z}} \right) \left( \vec{l}_{a_0 n^2 + a_1 n + a_2} = clen \langle a_0 - n/2, a_1 - n/2, a_2 - n/2 \rangle \right) \quad (5)$$

#### 3.2 lattice\_populate\_fcc

Creates, populates, and prunes a spherical nanoparticle with radius  $r$ , lattice parameter  $c$ , and centered at  $latt\_center$ . There is an internal overestimation parameter  $f$ , to ensure full population, currently set at 2.

$$n = \text{int} \left( \text{floor}(2rf) \right)$$

$$\left( \forall a_i, i \in [-n/2, n/2]_{\mathbb{Z}}, [0, 2]_{\mathbb{Z}} \right) \left( \vec{l}_{a_0 n^2 + a_1 n + a_2} = c((a_0)\vec{v}_0 + (a_1)\vec{v}_1 + (a_2)\vec{v}_2) \right)$$

Where  $\vec{v}_i$  are the primitive vectors for a fcc lattice

$$\begin{aligned} \vec{v}_0 &= \langle 0, 0.5, 0.5 \rangle \\ \vec{v}_1 &= \langle 0.5, 0, 0.5 \rangle \\ \vec{v}_2 &= \langle 0.5, 0.5, 0 \rangle \end{aligned}$$

Then, mark vectors outside the radius:

$$\left( \forall \vec{v} \in \vec{l} \right) \left( ||\vec{v} - latt\_center|| > r^2 \implies \vec{v} \rightarrow \langle 0, 0, 0 \rangle \right) \quad (6)$$

Now remove all zero vectors from  $\vec{l}$  to prune the nanoparticle.
